Introduction

Vincent van Proosdij, Senior
Consultant

Tobias Meier, Senior Consultant (QS)

Agenda

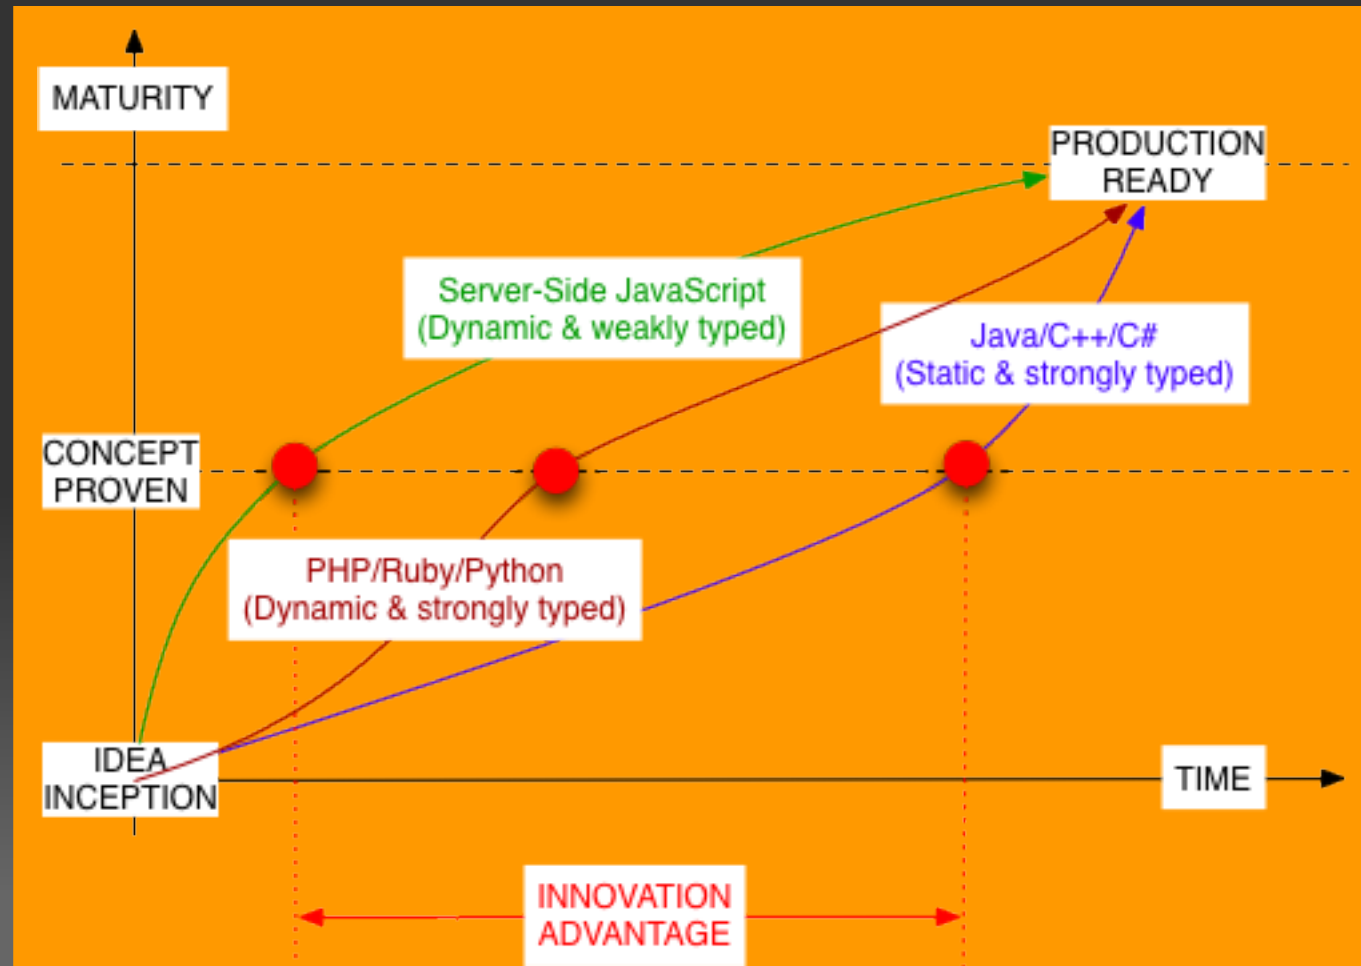

- what is nodejs
 - coffeescript introduction
 - some httpserver demos
 - more nodejs details
 - npm package management
 - build a website tracking demo
-
- some history. ryan
 - (was) most watched repo on github <https://github.com/popular/watched>

Node is:

- a set of **bindings** to V8 for non-browser work: http, sockets, files, etc.
- only exposes **non-blocking**, async interfaces 
- only **one** thread, one call stack (like the browser)
- has killer http support
- not a webframework (like rails/django...)
 - but it could be (express/geddy etc)
- runs **natively** on windows

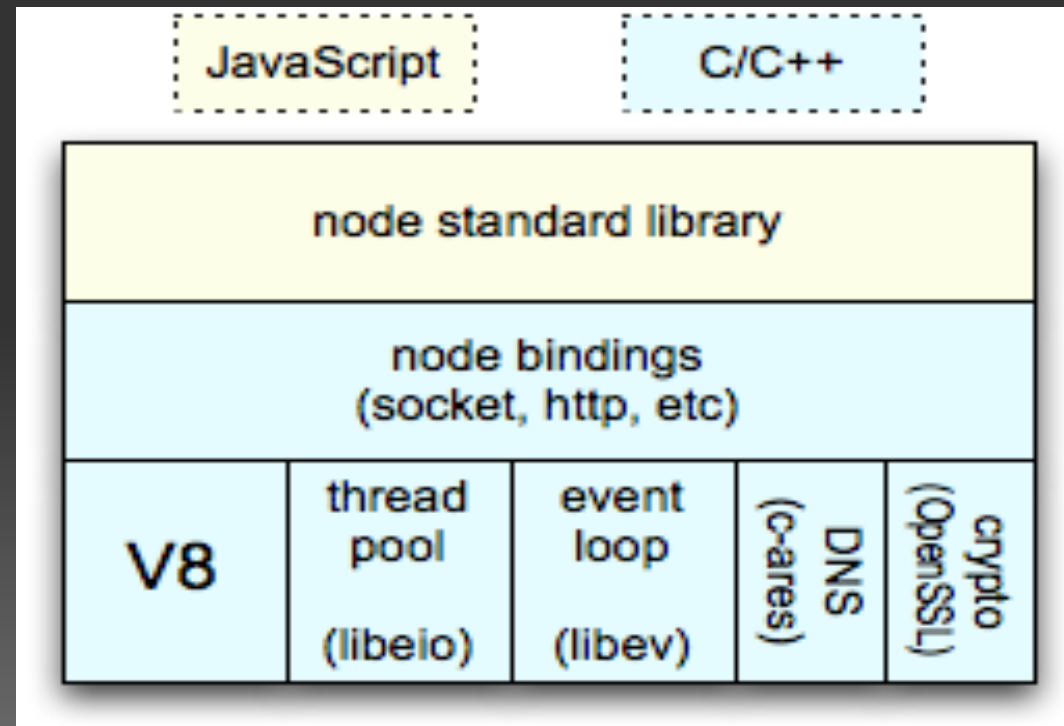

Node is also: great for innovation

- trying more ideas in less time
- time to production identical
- after concept more time is needed for checks and tests

Overall architecture:

- V8 compiles the source JavaScript directly to **machine code** the first time it is executed. There is no intermediate bytecode format and no JS interpreter.
- node.js **relies** on libev for the event loop, libeio for asynchronous I/O
- A standard library in **JavaScript** is supplied. This provides access to the underlying C++ implementation

CoffeeScript

is:

- a javascript replacement
- compiles coffeescript > > javascript
- ruby/python inspired

why:

- less code
- readable
- runs great with node
- js good parts only (subset)

highlights:

- indenting/ curly braces
- functions ->
- variable scoping (this?)

Hello world demo:

```
coffee .\01_web_hello_world.coffee
```

```
http = require "http"
```

```
server = http.createServer (req, res) ->  
  res.writeHead 200, "Content-Type": "text/plain"  
  res.write "Hello\n"  
  setTimeout ->  
    res.end "World\n"  
    , 3000  
  server.listen 1337, "127.0.0.1"
```

The eventloop

- I/O is **expensive**, so waiting happens. (cache/ram/disk/network)
- Application runs a main **event loop**
- **Nothing** new: EventMachine (ruby), Twisted (python)
- **Pattern** used already by JavaScript in Web Browsers

request handling solutions:

- synchronous
 - wait for next request
- fork a new process
 - too many processes
- start a new thread
 - thread per request cost lots of memory

node processing model

Eventloop demo:

```
coffee .\02_pulser_shows_events.coffee
```

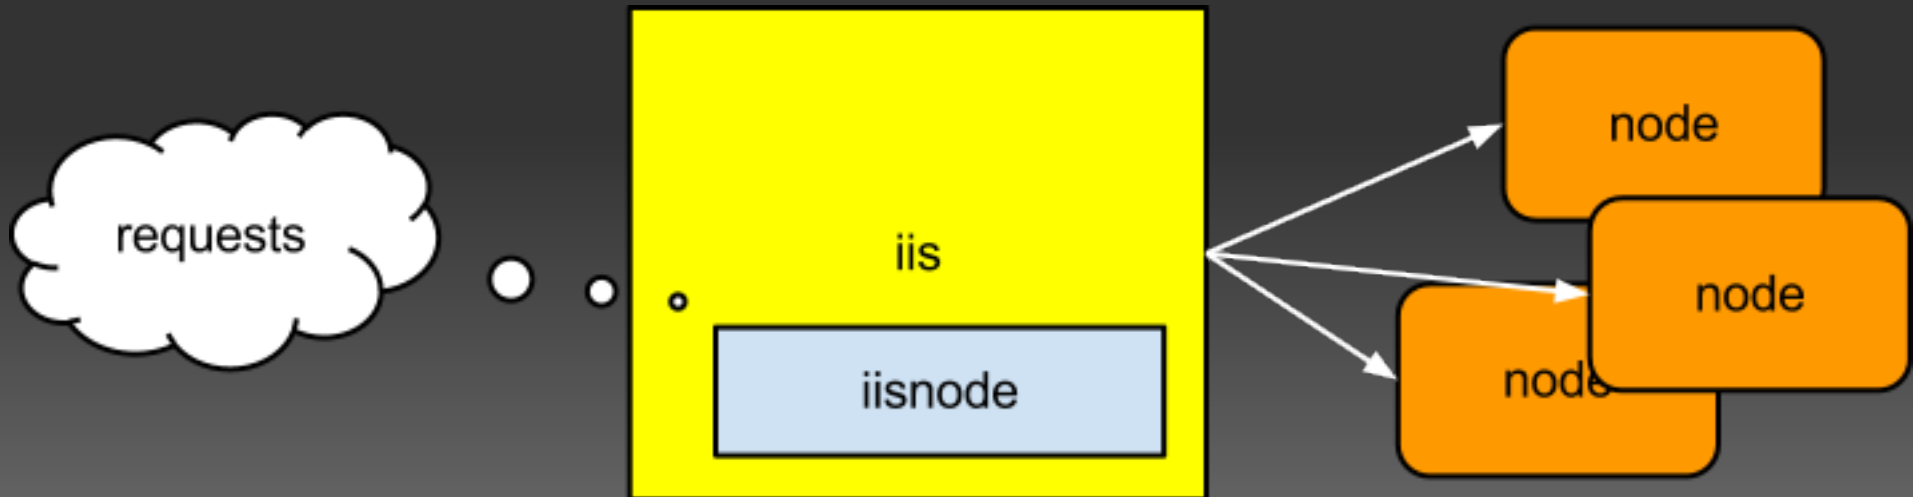

Node never sleeps demo:

`coffee .\03_node_never_sleeps.coffee`

- Time taken for tests: 2.053 seconds

Scalability

- node is **single** threaded, a single process
- to scale over multi-core, multi-machine > start **more** node instances.
- **prefork** instances with node-webworker or iisnode, like a load-balancer (not built-in)
 - ^^ future node versions will provide this in the core
- memory **isolation** enforced by process boundary

Package Management

- **repository** : search.npmjs.org or toolbox.no.de

- **scope**: global (-g) and application

- **usefull packages**

- [web] connect, express
- [testing] jasmine-node
- coffeescript, socket.io

- **npm commands**

- npm install coffee-script
- package.json
- npm install .
- npm ls
- npm search coffee

```
{
  "name": "dashboard",
  "version": "0.0.1",
  "dependencies": {
    "coffee-script": "1.2.0",
    "mongodb": "0.9.7",
    "socket.io": "latest",
  }
}
```

Modules

- **CommonJS** provides namespaces and scoping to nodejs
 - require `'...'` (like *using* or *import*)
 - exports

<http://www.commonjs.org/>

http.js

```
.  
server = function(){  
  .....  
}  
....  
exports.server = server
```

index.js

```
var http = require('http')  
  
http.server.....
```

Hosting??????????

- local
- web

website tracking demo:

a test client and a tracking server

Questions ?!
